

Anagram Group Finder

Problem

Given an array of words, group the words that are anagrams of each other into separate groups. Two words are anagrams if they contain exactly the same letters with the same frequency, just arranged differently. Do not use any built-in anagram-checking or sorting library build the comparison logic yourself using loops.

Sample Input

```
["listen", "silent", "enlist", "google", "banana"]
```

Sample Output

Group 1: listen, silent, enlist

Group 2: google

Group 3: banana

Explanation

"listen", "silent", and "enlist" all contain the letters l, i, s, t, e, n in equal frequency, so they form one group. "google" and "banana" don't match any other word's letter frequency, so each forms its own group.
